Analysis of Complexity

Dov Kruger

Department of Electrical and Computer Engineering Stevens Institute of Technology

September 28, 2022

Assumptions of Data Structures/Algorithms

All operations take unit time so slow or fast does not matter

Example

x * y and x + y are both just unit time All memory access is

considered uniform (cache does not matter)

Complexity

Complexity is a measure of how much time or space is used by a program as a function of the size of the problem

 $\label{eq:constraint} \mbox{Big-O} \quad {\cal O}() \quad \mbox{worst case, the most time (or space) the algorithm}$ will take

Omega $\Omega()$ best case (the shortest possible time to complete)

For the special case where $O() = \Omega()$ theta $\theta()$

Later, we will also talk about **amortized complexity**, the average case

Worst case and Best case: Finding a number in a List

$$1, 3, 4, 19, 20, 2, 16, 5, \dots, n = 10^6$$

how long to determine whether the number 9 is in the list? O()

or for this list?

$$9, 3, 4, 19, 20, 2, 16, 5, \dots, n = 10^6$$

 $\Omega()$

Worst case and Best case: Sum a List

$$1+4+6+19+20+...+n=10^6$$

Q: How long to compute the sum of the list? O()

Q: Is there any way to end early? $\Omega()$

Worst case and Best case: Sum a List

$$1+4+6+19+20+...+n=10^6$$

Q: How long to compute the sum of the list? O()

Q: Is there any way to end early? $\Omega()$

NO! The only way to compute the sum is to add all the numbers

Because $O(n) = \Omega(n)$ summing a list is $\theta(n)$

Common Misconception/Mistake for $\Omega()$

Remember that complexity is the asymptotic behavior **as the problem grows**

- You just saw the problem of summing a list on the last page
- Many people understand it, but then sometimes, will do the following

```
sum(list) O(n) \Omega(1) when n=1
```

No! When n=1, the problem is small, of course complexity is 1

- Question: When n is BIG, is there any way of ending early?
- Answer: No. To compute the sum, you must sum ALL THE NUMBERS

Therefore $\Omega(n)$ not $\Omega(1)$

moral: Saying $\Omega(1)$ when n=1 is meaningless

O() Formal Derivation

Big-O is formally defined as

$$f(n) = O(g(n))$$
 means there exists a constant c such that $f(n) \leq cg(n)$ for some n

Examples:

$$\begin{array}{ll} f(n)=2n & O(?) & \text{pick } c=3, 2n \leq cn, \text{ therefore } O(n) \\ f(n)=.00001n^2 & \text{pick } c=1, .00001n^2 \leq cn^2 \text{ therefore } O(n^2) \end{array}$$

In other words, the constant in front of the term does not matter

O() Slightly More Complicated Example

$$g(n) = .01n^3 + 5n^2 + 10^9$$

$$O(q(n)) = ?$$

All we have to do is pick c bigger than .01 As n grows, n^3 will become the biggest term very quickly

suppose c = 1, $cn^3 > g(n)$ for some n?

Of course: n=1 no, since .01(1)+5(1)+109 the constant is big At n=1000, $.01*(1000)^3$ is already 10,000,000. At n=10000, $1n^3$ is already bigger than g(n)

O() Informal Derivation

Less formally: as n grows, the highest power of n is dominant, constants are irrelevant

Examples:

$$\begin{array}{ll} O(n+5) \text{ as } n \text{ grows (think } n=10^6) \text{ the } 5 \text{ is insignificant } O(n) \\ O(3n) = & O(n) \\ O(.001n) = & O(n) \\ O(n^2+n) & \text{as n grows, the } n^2 \text{ term grows much faster.} \\ & n^2 \text{ (the leading term) dominates therefore } O(n^2) \\ O(5000n+.00001n^3+\sqrt{n}) = O(n^3) \end{array}$$

All Logs have a Constant Factor

For the special case of $O(\log n)$ it does not matter whether it is

- $\log_2 n$
- $\log_3 n$
- Any other base

The reason is that all logs are related by a constant

$$\log_2 n = c \, \log_3 n, \qquad c = \log_2 3$$

O() for Various Functions

$$g(n) = n^{3} + 1000000n^{2}$$

$$g(n) = n + n$$

$$O()$$

$$g(n) = \log n + n$$

$$O()$$

$$g(n) = (n + n)^{2}$$

$$O()$$

$$g(n) = 4n^{3} + 1000000n^{2}$$

$$O()$$

$$g(n) = 4n^{4} + 1000000n^{3}$$

$$O()$$

$$g(n) = 4n^{4/3} + 1000000n$$

$$O()$$

$$g(n) = 4\sqrt{n} + \log n$$

O() for Various Functions

$$g(n) = n^{3} + 1000000n^{2} \qquad O(n^{3})$$

$$g(n) = n + n \qquad O(n)$$

$$g(n) = \log n + n \qquad O(n)$$

$$g(n) = (n + n)^{2} \qquad (2n)^{2} = 4n^{2} = O(n^{2})$$

$$g(n) = 4n^{4} + 1000000n^{3} \qquad O(n^{4})$$

$$g(n) = 4\sqrt{n} + \log n \qquad O(\sqrt{n})$$

Test Yourself

How Functions Grow Asymptotically (Polynomials)

As n grows, n^2 is obviously a lot worse. And n^3 is even worse \mbox{Try} to find algorithms that are as low as possible on the complexity scale

n	n^2	n^3
1	1	1
10	100	1000
100	10^{4}	10^{6}
1000	10^{6}	109
10^{6}	10^{12}	10^{18}

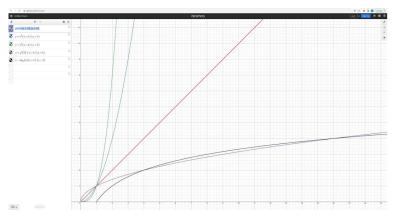

How Functions Grow (Log and Square Root)

n	log_2n	\sqrt{n}
1	0	1
10	3.3	3.3
100	6.7	10
1000	9.9	33
10^{6}	20	1000
109	30	30,000
10^{12}	40	10^{6}

Key Skill: Reading Code and Analyzing Complexity

It is vital to be able to read code or pseudocode

- Analyze complexity of current code
- Determine if possible to improve?

We will analyze the following programming features

- Loops
- Loops Containing if Statements
- Sequential loops
- Nested loops
- Recursive Functions

Complexity of Loops

Pseudocode or real programming language? In this course we don't care! You should be able to state your algorithm or analyze either

```
for i \leftarrow 1 to n //O() \Omega()
end
    for (int i = 0; i < n+1; i++) {//O()
    for (int i = 1; i \le n+500; i++) {//O()
    for (int i = 17; i < 1000*n; i += 3) {//O()
```

Complexity of Loops - Answers

Pseudocode or real programming language? In this course we donât care! You should be able to state your algorithm or analyze either

```
for i \leftarrow 1 to n //O(n) \Omega(n)
end
    for (int i = 0; i < n+1; i++) {//O(n)
    for (int i = 1; i <= n+500; i++) {//O(n)
    for (int i = 17; i < 1000*n; i += 3) {//O(n)
```

Nonlinear Loops

```
for (int i = 1; i \le n; i *= 2) { //O()
for (int i = 1; i \le n; i *= 3) { //O()
for (int i = 1; i \le n; i = i * 2 + 3) { //O()
```

Nonlinear Loops – answers

```
for (int i = 1; i \le n; i \ne 2) {//O(log n)
for (int i = 1; i \le n; i *= 3) {// O(log n)
for (int i = 1; i \le n; i = i * 2 + 3){//O(log n)}
```

Logarithmic Complexity

```
Which is faster? n=10^6\quad 1,2,4,8,16,32,64\dots for (int i = 1; i <= n; i *= 2) { // O() } n=10^6\quad 1,3,9,27,81,\dots for (int i = 1; i <= n; i *= 3) { // O() }
```

Did you know? All logs differ by only a constant factor $\log_2(n) = c \, \log_3 n$

Complexity of Loops Containing if statements

```
array \leftarrow [9, 1, 2, 3, 6, ...] list has length n
complexity to find a number in the list?
linear_search(array, target)
  for i = 0 to length (array) -1 //O(?)
     if array[i] == target // \Omega(?)
       return i
    end
  end
  return -1
end
```

Complexity of Loops Containing if statements: Answers

```
array \leftarrow [9, 1, 2, 3, 6, ...] list has length n
complexity to find a number in the list?
linear_search(array, target)
  for i = 0 to length (array) -1 //O(n)
     if array[i] == target // \Omega(1)
       return i
    end
  end
  return -1
end
```

Test Yourself

Try to analyze the code snippets and determine the complexity

Complexity of Sequential and Nested Loops

```
// O(?)
for (int i = 0; i < n; i++) {
                                             //0()
for (int i = 0; i < n; i++) {
                                             //0()
//0()
for (int i = 0; i < n; i++) { for (int j = 1; j <=n; j++) {
```

Complexity of Sequential and Nested Loops, answers

```
// n+n = 2n = O(n)
for (int i = 0; i < n; i++) {
                                   //O(n)
for (int i = 0; i < n; i++) {
                                   //O(n)
//O(n^2)
for (int i = 0; i < n; i++) {
  for (int j = 1; j <= n; j++) { //O(n)
```

Complexity of Nested Loops, part 2

In this case notice the inner loop depends on the outer one

```
for (int i = 0; i <= n; i++) { // O(?)
    for (int j = 1; j <= i; j++) { // O(?)
    }
}</pre>
```

First time inner loop executes 1, second time 2, then $3,4,\dots n$ Total computation $=1+2+3+\dots+n=?$

Complexity of Nested Loops, part 2, answer

In this case notice the inner loop depends on the outer one

```
for (int i = 0; i <= n; i++) { // O(n)
    for (int j = 1; j <= i; j++) { // avg = n/2
    }
}</pre>
```

First time inner loop executes 1, second time 2, then $3,4,\ ...n$ Total computation = $1+2+3+\ ...\ +n=n(n+1)/2=O(n^2)$

Nested Loops, part 3

What is the total complexity of this nested loop?

```
//O(?)
for (i = 1; i <= n; i++) { // O()
  for (j = 1; j < i; j *= 2) { // O()
  }
}
```

Nested Loops, part 3 (answer)

What is the total complexity of this nested loop?

```
//O(n log n)
for (i = 1; i <= n; i++) { // O(n)
  for (j = 1; j < i; j *= 2) { // O(log n)
  }
}
```

Nested Loops, part 4

This time, the outer loop is logarithmic, and the inner one goes up to the outer variable

Surprise! It is not the same result

```
//O(?) for (i = 1; i <= n; i *= 2) { //O() for (j = 1; j <= i; j ++) { //O() } }
```

Nested Loops, part 4 (answer)

This time, the outer loop is logarithmic, and the inner one goes up to the outer variable

Surprise! It is not the same result

Deriving Sum of Powers of 2

$$1 + 2 + 4 + 8 + \dots + n/2 + n = ?$$

Informally:

$$1+2+4+8+16+32+64=127(2n-1)$$
 therefore $O(2n)=O(n)$

Formally:

[equation for google doc here. !@\$!@ google does not do equations in slides]

Memorize two Equations

Summary: you don't need to memorize too many equations in this course, but you do need these two

$$\sum_{i=1}^{n} i = n(n+1)/2 = O(n^2)$$

$$\sum_{i=1}^{\infty} \frac{1}{2^i} = \frac{1}{1} + \frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \dots + \frac{1}{n/2} + \frac{1}{n} = 2$$

Test Yourself

Analyze these real code snippets and try to determine complexity

Recursion

A recursive function is one that

- Calls itself
- Has a termination or base-case condition

Example:

```
\begin{array}{l} \mbox{factorial} \left( n \right) \\ \mbox{if } n <= 0 \\ \mbox{return } 1 \ // \ \mbox{termination or base case} \\ \mbox{end} \\ \mbox{return } n \ * \ \mbox{factorial} \left( n - 1 \right) \\ \mbox{end} \end{array}
```

Recursion Uses a Stack

Factorial example is tail recursion and is equivalent to a loop Implemented using a stack

factorial(5)=5*factorial(4)	5 * 24 = 120
factorial(4)=4*factorial(3)	4 * 6 = 24
factorial(3)=3*factorial(2)	3 * 2 = 6
factorial(2)=2*factorial(1)	2 * 1 = 2
factorial(1)=1*factorial(0)	1 * 1 = 1
factorial(0)=1(base case)	

Tail Recursion Complexity

The factorial example is called tail recursion because the last act of the function is to call itself

Complexity:
$$O(n) + O(n) = O(2n) = O(n)$$

Tail recursion can be automatically turned into a loop

For example, C++ will turn the previous code into the equivalent of:

```
int prod = 1;
while (n > 0)
prod *= n--;
```

Explosive Recursion: Multiple Calls

Tail recursion like factorial is efficient

Unfortunately recursive functions that call themselves multiple times are exponential

Example: Fibonacci

The fibonacci series starts with 1,1.

Each new number is the sum of the previous two.

$$1, 1, 2, 3, 5, 8, 13, 21, 34, 55, \dots$$

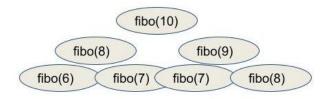

Fibonacci, Iteratively

The most direct way to compute the Fibonacci numbers is with a loop:

```
uint64_t fibo(uint64_t n) {
  uint64_t a = 1, b = 1, c;
  for (uint64_t i = 0; i < n; i++) { //O(n)
      c = a + b;
      a = b;
      b = c;
  }
  return c;
}</pre>
```

Fibonacci, Recursive

A recursive definition of fibonacci is simple, but inefficient:

Recursive Exponential Explosions

Like a chain reaction, a recursive function that calls itself multiple times is exponential

In this case, fibo called itself two times, so the cost is 2n

This means that fibo(10) is not 10 times worse than fibo(1), it is $2^{10}=1024$ times worse

 $\mathsf{fibo}(20) = 1024$ times the work of $\mathsf{fibo}(10)$

fibo(30) = 1024 times the work of fibo(20)...

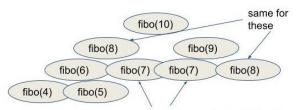

Dynamic Programming: Turn $O(2^n) \to O(n)$

It is possible to solve fibonacci in O(n)

Dynamic programming is a general technique to make exponential recursion more efficient by remembering previous answers.

Also called memoization

these 2 are redundant. And the entire tree under them will be redundant

Dynamic Programming: Never Recompute an Answer

Test Yourself
